Because electrons behave as both bodies and waves, they can interfere with each other supportively or negatively, causing to changes in transport properties. The Aharonov-Bohm effect, a excellent example, demonstrates how electrons are affected by a magnetic field even when they do not pass across it directly, purely due to quantum interference. This effect underscores the wave-like nature of electrons and the refined effects of quantum mechanics.

Furthermore, the Enrico Fermi School's courses likely address topics such as superconductivity in mesoscopic systems, wherein electron pairs collapse into a coherent quantum state, resulting to zero resistance. This occurrence finds important applications in manifold technologies, for example superconducting quantum interference devices (SQUIDs), employed for highly precise magnetic field measurements.
